1. ROC Methodology

The network output classifies voxels in the tumor as IDH mutated or IDH wildtype. The percentage of IDH-mutated voxels was computed for the network output for each subject in the test set by dividing the predicted IDH-mutated voxels by the total number of predicted voxels in each tumor. The percentage of mutated voxels can be viewed as a network output prediction likelihood of the tumor being IDH mutated. Note that, in the manuscript, majority voting (the 50% threshold) was used to determine IDH prediction. For the ROC analysis, the percentage of IDH-mutated voxels was sorted and used as separate thresholds (cut points) to determine IDH mutation status for the subjects across the test set for each new cut point. The resulting predicted IDH class membership was compared to the ground truth values to determine sensitivity (true-positive rate) and 1- specificity (false-positive rate) at each threshold. The resulting values were plotted using R programming to obtain an ROC curve (true-positive rate against false-positive rate). Routines in R programming were used to fit the curves and determine the area under the curve (AUC). This procedure was repeated for both T2-net and MC-net and their two training combinations. Smoothed curves were used to facilitate displaying the figure.

Table S1. Training subjects and corresponding IDH status.

Subject ID	IDH Status
